Quality measure

Instead of using the Delaunay quality measure of a tetrahedron (minimum solid angle) in mesh quality improvement operations, we aimed for a quality measure which would penalize both flat tetrahedra, characterized by near-zero volume despite the fact that the distances between their vertices (edge lengths) can be large.

We have chosen to improve the volume-length ratio of a tetrahedron:

$$Q(\sigma)=6\sqrt{2}\frac{V(\sigma)}{l_{rms}^3},$$

where V(t) is the oriented volume of a tetrahedron t, and $I_{\rm rms}$ is the average (root-mean-squared) of the lengths of its edges:

$$I_{\rm rms} = \sqrt{\frac{l_{12}^2 + l_{13}^2 + l_{14}^2 + l_{23}^2 + l_{24}^2 + l_{34}^2}{6}}.$$

Examples 000000 000

The purpose of detail control is to ensure that the embedding mesh has enough Steiner vertices, so that it is flexible enough to accomodate changes to the interface and, on the other hand, to make sure that the number of Steiner vertices does not increase too much, in order to keep the performance efficient.

We utilize two operations:

- **edge split**: for long edges connecting two interface vertices, or an interface vertex with a boundary vertex;
- edge collapse: for short edges, not connected to either the interface or the boundary of the embedding mesh, as long as it increases the minimum quality locally or does not decrease it below a certain threshold value.

Implementation O Examples

Interface topology changes

Whenever two parts of the interface are about to collide, nearly degenerate tetrahedra begin to appear in the mesh. We are producing interface topology changes by removing those tetrahedra. We do it in two ways;

- *tetrahedron re-labelling*: switching the label of a tetrahedron from *outside* to *inside* (or the other way round) if it is "squeezed" between two parts of the interface.
- *degeneracy removal*: removing nearly flat tetrahedra by "flattening" them and replacing with 4, 3 or 2 faces. Similarly, we remove degenerate (nearly colinear) faces and degenerate (very short) edges.

Implementation

- The 2D DSC implementation is built on top of the *half-edge* data structure available in the GEL library.
- The 3D DSC implementation relies on our own C++ implementation of the Incidence Simplicial data structure for 3D simplicial complexes by de Floriani et al.
- In its current form, the 3D DSC algorithm requires a triangle mesh as an input. This triangle mesh is then normalized and tetrahedralized on the inside and on the outside using TetGen (the outside mesh is bounded by a sparsly subdivided $(-1; -1; -1) \times (1; 1; 1)$ box).
