 - Bipartite Graphs

Undirected graphs

• Undirected graph. Set of vertices pairwise joined by edges.

- Why graphs?
 - Models many natural problems from many different areas.
 - Thousands of practical applications.
 - Hundreds of well-known graph algorithms.

Applications of Graphs

Graph	Vertices Edges		
communication	computers	cables	
transport	intersections	roads	
transport	airports	flight routes	
games	position	valid move	
neural network	neuron	synapses	
financial network	stocks	transactions	
circuit	logical gates	connections	
food chain	species	predator-prey	
molecule	atom	bindings	

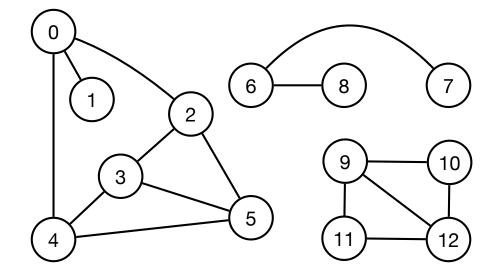

Terminology

- Undirected graph. G = (V, E)
 - V = set of vertices
 - E = set of edges (each edge is a pair of vertices)
 - n = |V|, m = |E|
- Path. Sequence of vertices connected by edges.
- Cycle. Path starting and ending at the same vertex.
- Degree. deg(v) = the number of neighbors of v, or edges incident to v.
- Connectivity. A pair of vertices are connected if there is a path between them

Undirected Graphs

- Lemma. $\sum_{v \in V} deg(v) = 2m$.
- Proof. How many times is each edge counted in the sum?

Algoritmic Problems on Graphs

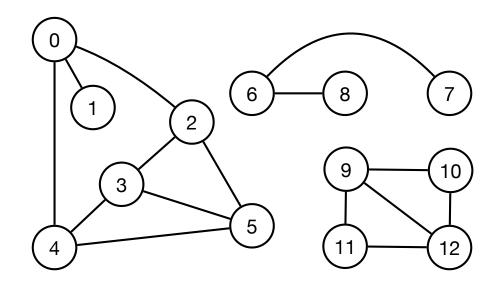

- Path. Is there a path connecting s and t?
- Shortest path. What is the shortest path connecting s and t?
- Longest path. What is the longest path connecting s and t?
- Cycle. Is there a cycle in the graph?
- Euler tour. Is there a cycle that uses each edge exactly once?
- Hamilton cycle. Is there a cycle that uses each vertex exactly once?
- Connectivity. Are all pairs of vertices connected?
- Minimum spanning tree. What is the best way of connecting all vertices?
- Biconnectivity. Is there a vertex whose removal would cause the graph to be disconnected?
- Planarity. Is it possible to draw the graph in the plane without edges crossing?
- Graph isomorphism. Do these sets of vertices and edges represent the same graph?

Introduction to Graphs

- Undirected Graphs

- Depth-First Search
 - Connected Components
- Breadth-First Search
 - Bipartite Graphs

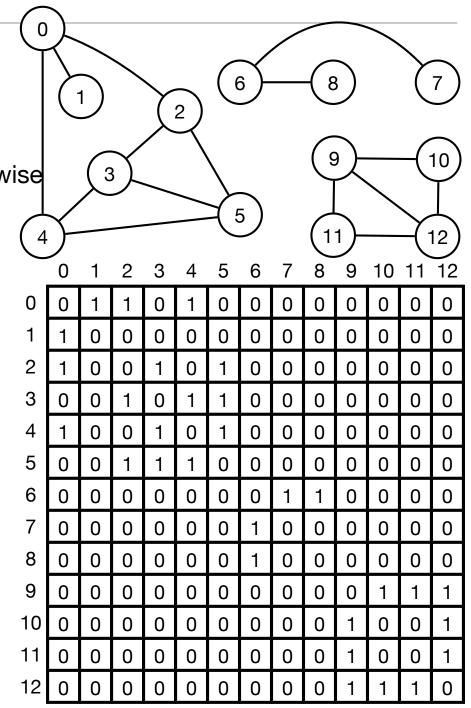

Representation

- Graph G with n vertices and m edges.
- Representation. We need the following operations on graphs.
 - ADJACENT(v, u): determine if u and v are neighbors.
 - NEIGHBORS(v): return all neighbors of v.
 - INSERT(v, u): add the edge (v, u) to G (unless it is already there).

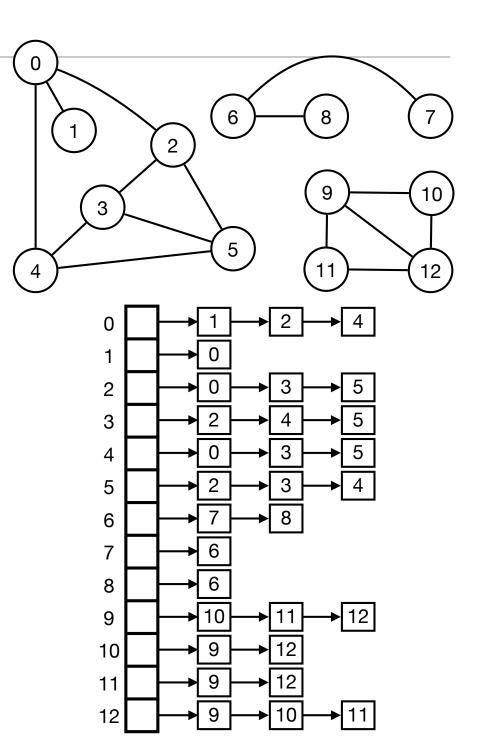

Adjacency Matrix

- Graph G with n vertices and m edges.
- Adjacency matrix.
 - 2D n \times n array A.
 - A[i,j] = 1 if i and j are neighbors, 0 otherwise
- Complexity?
- Space. O(n²)
- Time.
 - ADJACENT and INSERT in O(1) time.
 - NEIGHBOURS in O(n) time.

Adjacency List

- Graph G with n vertices and m edges.
- Adjacency list.
 - Array A[0..n-1].
 - A[i] is a linked list of all neighbors of i.
- Complexity?
- Space. $O(n + \sum_{v \in V} deg(v)) = O(n + m)$
- Time.
 - ADJACENT, NEIGHBOURS, INSERT O(deg(v)) time.

Representation

Data structure	Adjacent	NEIGHBOURS	INSERT	space
adjacency matrix	O(1)	O(n)	O(1)	O(n²)
adjacency list	O(deg(v))	O(deg(v))	O(deg(v))	O(n+m)

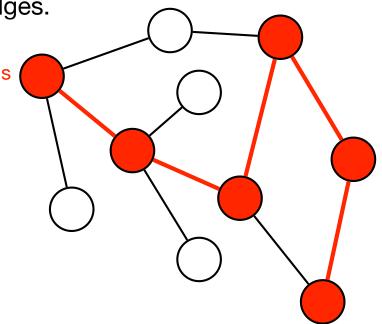

• Real world graphs are often sparse.

Introduction to Graphs

- Undirected Graphs
- Representation
- Depth-First Search
 - Connected Components
- Breadth-First Search
 - Bipartite Graphs

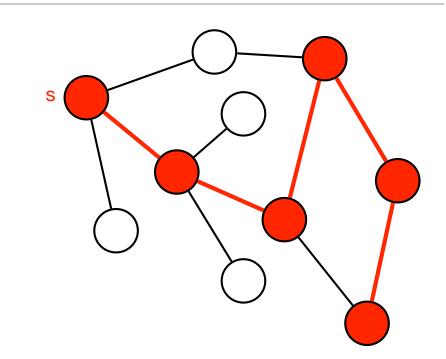

Depth-First Search

- Algorithm for systematically visiting all vertices and edges.
- Depth first search from vertex s.
 - Unmark all vertices and visit s.
 - Visit vertex v:
 - Mark v.
 - Visit all unmarked neighbours of v recursively.

- Intuition.
 - Explore from s in some direction, until we read dead end.
 - Backtrack to the last position with unexplored edges.
 - Repeat.
- Discovery time. First time a vertex is visited.
- Finish time. Last time a vertex is visited.

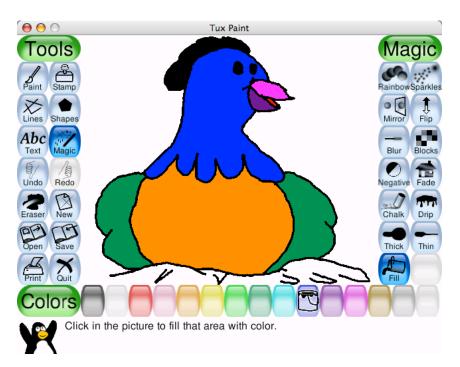

Depth-First Search

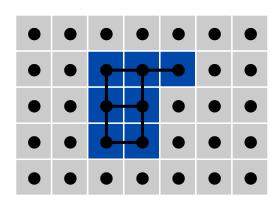

- Time. (on adjacency list representation)
 - Recursion? once per vertex.
 - O(deg(v)) time spent on vertex v.
 - \implies total O(n + $\sum_{v \in V} deg(v)$) = O(n + m) time.
 - · Only visits vertices connected to s.

Flood Fill

• Flood fill. Chance the color of a connected area of green pixels.

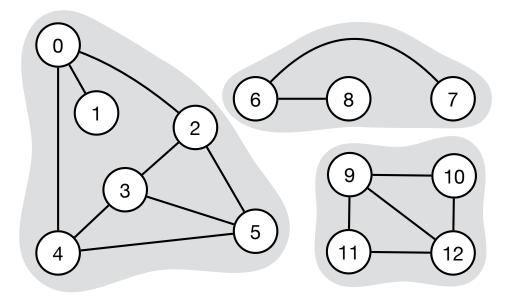

- Algorithm.
 - Build a grid graph and run DFS.
 - Vertex: pixel.
 - Edge: between neighboring pixels of same color.
 - · Area: connected component

Connected Components

• Definition. A connected component is a maximal subset of connected vertices.

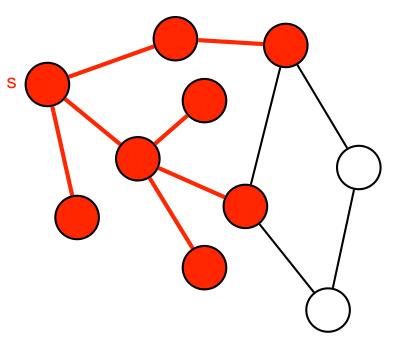

- How to find all connected components?
- Algorithm.
 - Unmark all vertices.
 - While there is an unmarked vertex:
 - Chose an unmarked vertex v, run DFS from v.
- Time. O(n + m).

Introduction to Graphs

- Undirected Graphs
- Representation
- Depth-First Search
 - Connected Components
- Breadth-First Search
 - Bipartite Graphs

Breadth-First Search

- Breadth first search from s.
 - Unmark all vertices and initialize queue Q.
 - Mark s and Q.ENQUEUE(s).
 - While Q is not empty:
 - v = Q.DEQUEUE().
 - For each unmarked neighbor u of v
 - Mark u.
 - Q.ENQUEUE(u).

- Intuition.
 - Explore, starting from s, in all directions in increasing distance from s.
- Shortest paths from s.
 - Distance to s in BFS tree = shortest distance to s in the original graph.

Shortest Paths

- Lemma. BFS finds the length of the shortest path from s to all other vertices.
- Intuition.
 - BFS assigns vertices to layers. Layer number i contains all vertices of distance i to s.
 L₁
 L₂

Lo

L₃

- What does each layer contain?
- L₀ : {s}
- $L_{1:}$ all neighbours of L_0 .
- $L_{2:}$ all neighbours of L_1 that are not neighbors of L_0
- L_3 : all neighbours of L_2 that neither are neighbors of L_0 nor L_1 .
- ...
- $L_{i\,:}$ all neighbours of $L_{i\text{--}1}$ that are not neighbors of any L_j for j < i--1
 - = all vertices of distance i from s.

Breadth-First Search

```
BFS(s)

mark s

s.d = 0

Q.ENQUEUE(s)

repeat until Q.ISEMPTY()

v = Q.DEQUEUE()

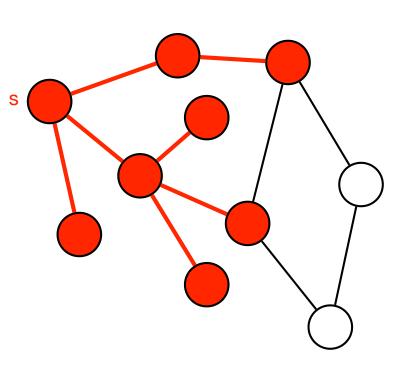

for each unmarked neighbor u

mark u

u.d = v.d + 1

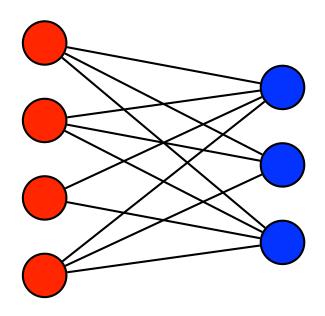

u.\pi = V

Q.ENQUEUE(u)
```

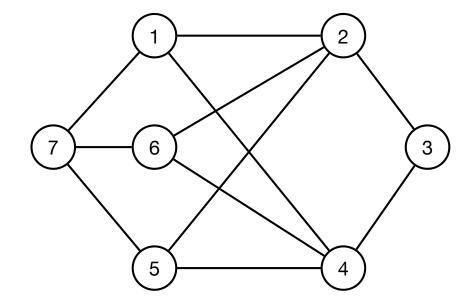

- Time. (on adjacency list representation)
 - Each vertex is visited at most once.
 - O(deg(v)) time spent on vertex v.
 - \implies total O(n + $\sum_{v \in V} deg(v)$) = O(n + m) time.
 - Only vertices connected to s are visited.

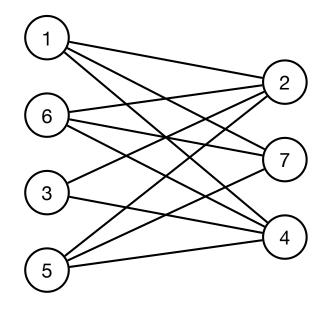

- Definition. A graph is bipartite if and only if all vertices can be colored red and blue such that every edge has exactly one red endpoint and one blue endpoint.
- Equivalent definition. A graph is bipartite if and only if its vertices can be partitioned into two sets V₁ and V₂ such that all edges go between V₁ and V₂.

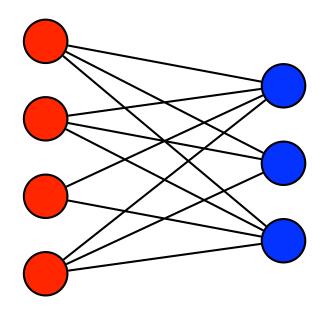

- Application.
 - Scheduling, matching, assigning clients to servers, assigning jobs to machines, assigning students to advisors/labs, ...
 - Many graph problems are *easier* on bipartite graphs.

• Challenge. Given a graph G, determine whether G is bipartite.

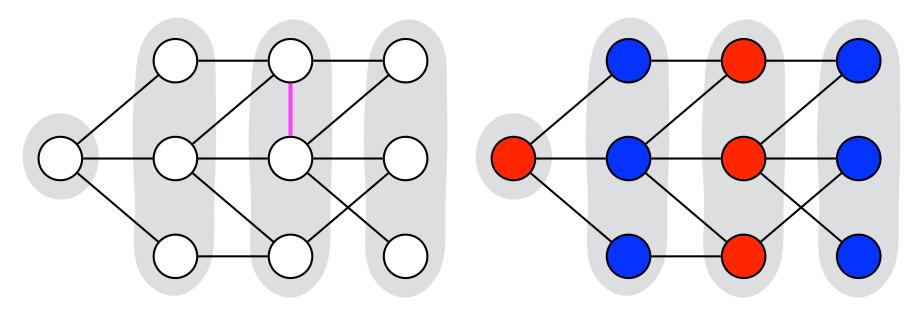

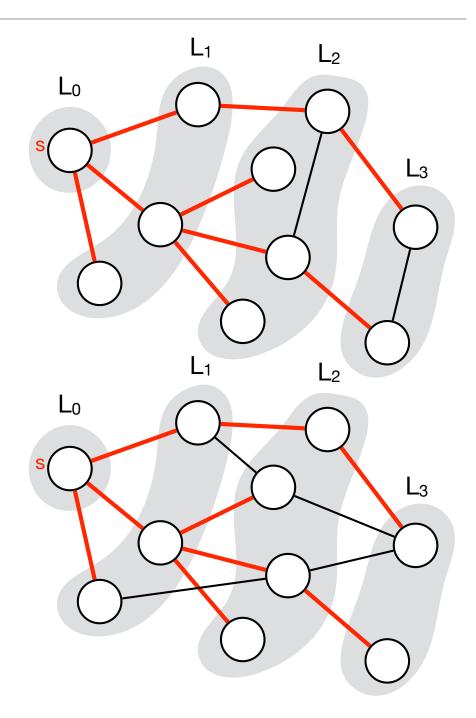

- Lemma. A graph G is bipartite if and only if all cycles in G have even length.
- Proof. \Longrightarrow
 - If G is bipartite, all cycles start and end on the same side.

- Lemma. A graph G is bipartite if and only if all cycles in G have even length.
- Proof. ←
 - Choose a vertex v and consider BFS layers L₀, L₁, ..., L_k.
 - All cycles have even length
 - $\bullet \implies$ There is no edge between vertices of the same layer
 - \implies We can colors layers with alternating red and blue colors.
 - \Longrightarrow G is bipartite.

- Algorithm.
 - Run BFS on G.
 - For each edge in G, check if it's endpoints are in the same layer.
- Time.
 - O(n + m)

Graph Algorithms

Algorithm	Time	Space
Depth first search	O(n + m)	O(n + m)
Breadth first search	O(n + m)	O(n + m)
Connected components	O(n + m)	O(n + m)
Bipartite	O(n + m)	O(n + m)

• All on the adjacency list representation.
